Schistosoma mansoni life cycle

Schistosomiasis is a neglected tropical disease caused by parasitic flatworms (schistosomes) that ranks second behind malaria in terms of human suffering in the tropical and subtropical areas. The life cycle of Schistosoma mansoni includes a vertebrate host (mostly humans and rodents) where sexual reproduction occurs and a snail vector where an asexual multiplication occurs. Transmission from the snail to the human host occurs in fresh waterbodies: hundreds of cercariae (with bifurcated tail) emerge daily from infected snails and these larvae actively seek and penetrate skin of the vertebrate host.

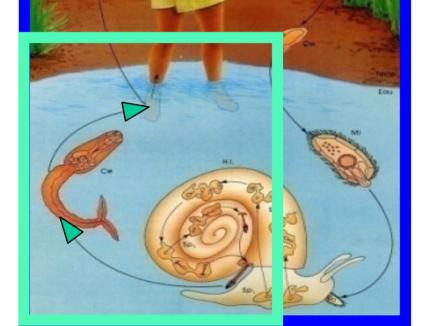

Cercarial emergence from infected snails follows a daily rhythm matching with the behavior of the targeted vertebrate host. For instance, Schistosoma mansoni, which causes intestinal schistosomiasis, exhibits two different chronotypes: (i) one adapted to the human where cercariae mainly emerge from the infected snail, Biomphalaria pfeifferi, with a peak around midday (diurnal chronotype) and (ii) one adapted to the nocturnal rodent, Rattus rattus, where cercariae mainly emerge during the night with a peak at 7 or 8 pm (nocturnal chronotype) (Mouahid et al. 2012 Trop. Med Int Health 17, 727-732 (2012)).

3

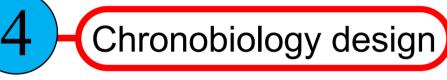

AIM

This project was designed to determine if the rhythm of the nocturnal chronotype is, or is not, circadian (i.e.= a rhythm that can persist under constant conditions (Kuhlman et al. 2018, Cold Spring Harb Perspect Biol 2018; 10:a033613).

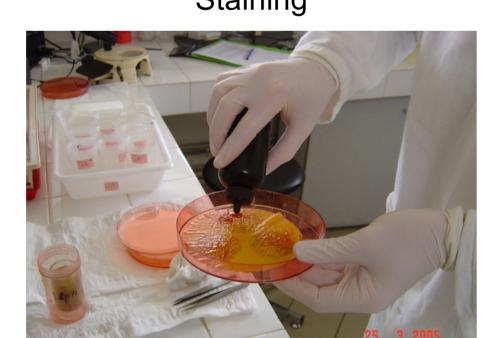

- We infected Biomphalaria pfeifferi snails with one miracidium each, using the nocturnal chronotype of S. mansoni.
- From an equilibrated 12 hr light_12 hr dark photoperiod, the infected snails were divided into two groups. Two experiments were conducted: (1) constant darkness, (2) photoperiod switch.
- \succ We kept constant temperature (25-26°C) all over the experiment.
- ➢ We analyzed the cercarial emergence pattern hourly, 24 hours a day, during 19 consecutive days. To collect the cercariae, each infected snail was transferred to a new beaker filled with well water; the collected cercariae were filtered, stained and counted under a binocular microscope.

CONCLUSION

The cercarial emission rhythm of the nocturnal *S. mansoni* chronotype DOES NOT follow a circadian rhythm, suggesting the absence of a canonical internal clock and the presence of an alternative mechanism for timing of cercarial emission.

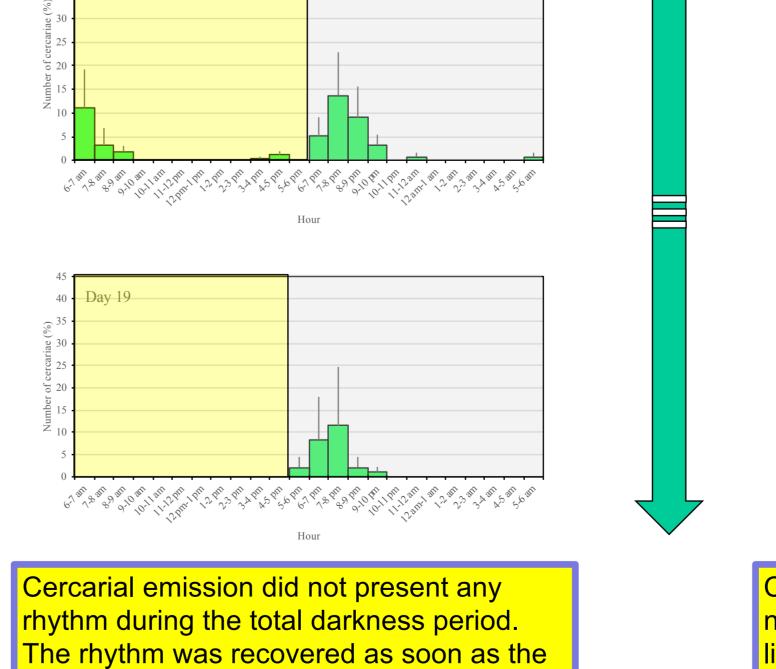

- Analyze time keeping in the diurnal chronotype of S. mansoni.
- Analyse the intra-molluscan development of the parasites during constant darkness and constant light (histological approach).

equilibrated photoperiod was restored.

Day 19 Cercarial emission remained predominantly nocturnal as soon as the switch (from 12hr light-12hr dark to 12hr dark-12hr light) was made.
